Problem	Points Possible	Earned
1	10	
2	10	
3	5	
4	5	
5	10	
TOTAL	40	

Problem 1 (10 points)**.** Suppose that $X_1, \ldots, X_{16}$ is a random sample from a $N(\mu, \sigma^2)$ distibution. The sample mean and sample variance equal 0.5 and $S^2 = 0.64$ respectively.

(a) (4 points) Is the test of $H_0 : \mu = 0$ vs. $H_1 : \mu \neq 0$ significant at level 0.01? [Show your calculations!]

(b) (2 points) Give a 90% confidence interval for μ.

(c) (4 points) Give a 95% confidence interval for σ^2.

Solution.

(a) We use the T-statistic, because σ^2 is unknown.

$$T = \frac{0.5 - 0}{\sqrt{0.64/16}} = 2.5\,.$$

The 0.005 critical value for a t-distribution with 15 degrees of freedom equals 2.947, when $\alpha = 0.01$. Since $2.5 < 2.947$, we do not reject. That is, the test is not significant.

(b) Recall that we want to locate the central 90% of the distribution, leaving 5% in each tail Since the 95% percentile of the t-distribution is $t_{15,0.05} = 1.753$, we have

$$0.5 \pm 1.753 \times \frac{\sqrt{0.64}}{4} = [0.1494, 0.8506]\,.$$

(c) We have the 0.025-th and the 0.975-th quantiles of the chi-squared distribution with $16 - 1 = 15$ degrees of freedom are 6.262 and 27.488, respectively. Recall that a confidence intercal for σ^2 is of the form

$$\left[\frac{(n-1)S^2}{\chi^2_{n-1,1-\alpha/2}}, \frac{(n-1)S^2}{\chi^2_{n-1,\alpha/2}} \right].$$

Thus, an interval for σ^2 is

$$\left[\frac{15 \cdot 0.64}{27.488}, \frac{15 \cdot 0.64}{6.262} \right] = [0.349,\ 1.533]\,.$$

$\square$

Problem 2 (10 points)**.** Suppose that $X_1, \ldots, X_{25}$ are i.i.d. with $N(\mu, 1)$ distribution. Consider the test of $H_0 : \mu = 0$ vs. $H_1 : \mu > 0$ with rejects H_0 if and only if $\bar{X} > 0.3$.

(a) (5 points) What is the significance level of this test?

(b) (5 points) What is the power of this test if $\mu = 0.1$?

Solution.

(a) The significance level is the probability of rejecting under H_0. Thus, since $\bar{X}$ has a $N(\mu, 1/25)$ distribution,

$$\alpha = P(\bar{X} > 0.3 \mid \mu = 0) = P(5\bar{X} > 1.5) = P(Z > 1) = 0.0668 .$$

(b) The power is the probability of correctly rejecting H_0. Thus,

$$\begin{aligned} P(\bar{X} > 0.3 \mid \mu = 0.1) &= P(5(\bar{X} - 0.1) > 5(0.3 - 0.1) \mid \mu = 0.01) \\ &= P(Z > 1) = 0.1587 \end{aligned}$$

□

Problem 3 (5 points)**.** You want to know if the average heights of a given tree species differs among two locations. In a sample of 14 trees from Location A, the mean and standard deviation are 10.2m and 2m, respectively. In Location B, a sample of 10 trees has a mean and standard deviation of 12.1m and 3m, respectively. Give a 90% confidence interval for the difference in expected heights between the two locations. Assume the populations have the same variances.

Solution. The pooled sample variance and standard deviation are

$$\begin{aligned} S_p^2 &= \frac{13 \cdot 2^2 + 9 \cdot 3^2}{22} = 6.0454 \\ S_p &= 2.459 \end{aligned}$$

The critical value for a t-distribution with 22 degrees of freedom is 1.717, so a 90% confidence interval is

$$(10.2 - 12.1) \pm 1.717 \times 2.459 \sqrt{\frac{1}{14} + \frac{1}{10}} = -1.9 \pm 1.748 \,.$$

□

Problem 4 (5 points)**.** Suppose that you test whether a coin is fair against the alternative that it is biased towards "heads", and out of 100 tosses, it lands heads 60 times. What is the approximate p-value of this test?

Solution.

$$\begin{aligned} P(X \geq 60) &= P\left(\frac{X - 50}{\sqrt{100(1/2)(1/2)}} \geq \frac{59.5 - 50}{\sqrt{100(1/2)(1/2)}} \right) \\ &\approx P(Z > 1.9) = 0.0287 \,. \end{aligned}$$

□

Problem 5 (10 points)**.** Suppose that $X_1, \ldots, X_n$ are i.i.d. with the pdf

$$f(x;\theta) = \theta x e^{-\theta x^2/2}.$$

(a) (5 points) Give the form of the GLRT of $H_0 : \theta = \theta_0$ vs $H_1 : \theta \neq \theta_0$. Your answer should specify the form of the rejection region in terms of a sufficient statistic, although the exact boundaries of the region do not need to be determined.

(b) (5 points) Use the fact that $\theta \sum_{i=1}^{8} X_i^2$ has a chi-squared distribution with 8 degrees of freedom to determine the exact rejection region corresponding to the test with $\alpha = 0.05$, when $\theta_0 = 2$ and $n = 8$.

Solution. The likelihood and log-likelihood functions equal, respectively,

$$L(\theta; x_1, \ldots, x_n) = \prod_{i=1}^{n} \theta x_i e^{-\theta x_i^2/2} = \theta^n \left(\prod_i x_i \right) e^{-\frac{1}{2}\theta \sum_i x_i^2}$$

$$\ell(\theta) = n \log \theta - \frac{1}{2}\theta \sum_i x_i^2 + \sum_i \log x_i .$$

To find the MLE (needed for GLR), we take the derivative, set to zero, and solve:

$$\ell'(\theta) = \frac{n}{\theta} - \frac{1}{2}\sum_i x_i^2 ,$$

yielding $\hat{\theta} = \frac{2n}{\sum_i x_i^2} = \frac{2n}{s}$, where $s = \sum_{i=1}^{n} x_i^2$ is a sufficient statistic. The GLR is

$$\Lambda(s) = \frac{L(\theta_0)}{L(\hat{\theta})} = \frac{\theta_0^n e^{-\frac{1}{2}\theta_0 s} \prod_i x_i}{(2n/s)^n e^{-\frac{1}{2}(2n/s)s} \prod_i x_i}$$
$$= (2ne)^{-n} (\theta_0 s)^n e^{-\theta_0 s/2}.$$

The GLRT rejects if and only if $\Lambda(s) < k_0$, where k_0 is chosen to guarantee the test has level α.

Since $\Lambda(s) < k_0$ if and only if $\theta_0 s < a_0$ or $\theta_0 s > b_0$, where a_0, b_0 are determined by k_0, the GLRT rejects if and only if $\theta_0 s < a_0$ or $\theta_0 s > b_0$. Values of a_0 and b_0 are selected to ensure the test has level α.

When $n = 8$ we know that, under $H_0 : \theta_0 = 2$, the statistic $2S$ has a chi-squared distribution with 8 degrees of freedom. The 0.025-th and 0.975-th percentiles of the distribution are 2.180 and 17.535, repectively.

Thus, a level 0.05 test rejects if and only if $2S < 2.180$ or $2S > 17.545$. □

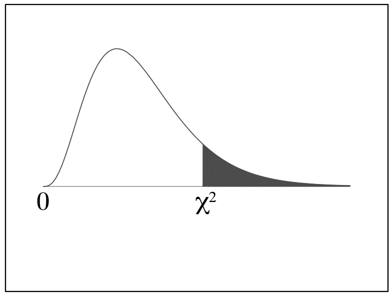
Chi-Square Distribution Table



The shaded area is equal to α for $\chi^2 = \chi^2_\alpha$.
